Listen to this one.

Playing renegade, hear a funny siren sound coming from the tower.

Boom, shuts off. I dont know what I did, so i turn it on, funny siren sound a gain. Im like, wtf.

So I pop her open, take a look and see that the main CPU fan is dusty, i take her apart, give her a nice cleaning, pop her where she should be and watch this time ot the startup.

It seems the fan goes at like 700 RPM when it should be usually doing 3500 (when we first bought it) They think its the "coolant chip" but im not convinced. No viruses, brand new, 3000\$ computer i dont see why it would do this to me.

IT the fan, definately. When i kick it (wrong thing to do but i was mad) It will boot up to about 2500 RPM for about 2 minutes, then die to 300-400 RPM

Any ideas? I downloaded Mother Board Monitor 5 and it works great, it shows my the temp of my CPU at crashes.

It reaches 100 Degrees C

Yes, Celcius by what it says.

I wanna fix this, but i dont want to take it 15 miles to get it repaired, any ideas?
