Will only work for a dedicated server.

You need to open the port that is in server.ini at "port=".

So: first of all, don't put '0' in there, fill in for exemple 5500.

Then go to your router admin and go to "port forwarding" (sometimes it is called "virtual server"). If you don't know how, check [www.portforward.com](http://www.portforward.com) for your router model.

Open the port 5500 (in my exemple but it can be any port as long as it's the one you enetred in "port=") and forward it to the internal IP of your server. To know the internal IP, go to start menu -> run -> cmd -> ipconfig. It should probably be smth like 192.168.x.x.

That should solve this annoying problem.
