IF you want a stable system, dont bother with SLI. Most motherboards that are so called "SLI" actually are just barely able to run 2 GPU's, and story with PSU's. Also, SLI means no overclocking unless your motherboard has PCI/AGP locks, and even then alot of things can go wrong. I returned my 2 mid range SLI cards, in exchange bought 1 high end card. Btw, if your using XP, it not meant for SLI, so things like chkdisk/f on bootup wont work, loading up safemode doesnt show, and little things like that give everyone problems
