Of all the billions of planets orbiting billions of stars in millions of galaxies... if life exists anywhere (and we can fairly assume that it does ), the odds against there being life elsewhere as well are absurdly low. Somewhere just by pure, dumb luck (or design, if you'd rather have it that way), there must be at least several hundred thousand more planets orbiting stars like our sun at exactly the right distance, in exactly the right place in their respective galaxies, with massive planets like Jupiter to gobble up all the 'roids. Out of all those many, there must be some on which the proper atmospheric conditions and lunar counterbalance exists in order to make life possible.

Honestly, the thought of there not being other life out there- and intelligent life, at that, given how long the universe has been around- is utterly incomprehensible to me.
