The basic answer is:

The ozone layer is comprised of the compound ozone (O<sub>3</sub>). Ozone reflects most of the sun's high intensity ultraviolet light, which is damaging to life. Greenhouse gases (water vapor, carbon dioxide, methane, etc, partially produced from pollution sources) don't reflect any of the sun's light, therefore does not act as a second ozone layer. They merely trap in some of the heat in the earth's atmosphere.

I should also add that greenhouse gases are necessary for survival on earth. Without them, temperatures would be entirely too cold. However excessive amounts of greenhouse gases do lead to higher temperatures on earth.

I will also add that natural sources produce 20 times the amount of greenhouse gases as humans.
