(all info gathered from popular science)

this is my kind of conversation, please prepare for another lecture this time on Warp Drives

there are a lot of ways man can achieve warp speeds but first I will start with man's latest strive toward achieving success. This started in WWII when German scientists started development of a "buzz bomb" which used a revolutionary engine that used a pulse detonation method that simply has an array of tubes and the ends of each tube were sealed off and there was an explosion in one tube then an explosion immediately after the first in the next tube and so on, but the Germans never really made it happen because the US and Russia stormed them and captured all of them and their research. Well, not some 20 years later the idea of this "pulse detonation" started to seem kind of a good idea, not they got a pulse detonation engine that goes about 400 cycles per second with 6 tubes creating hundreds of pounds of thrust in milliseconds using even less gas. An engine like this would be perfect for space ships and other things but there is still a way to go. Now to actual warp engines, first we start with radiation sails, simple design where most of the ship is a huge sail that lets radiation pass through one side but not the other building up radiation pressure on one side and not the other pushing the ship forward.

Next we have real warp where time and space gets warped with a Disjunction drive which would be creating a field and separating reactions of the field from the field creating forces that would accrete with the field without the field

Then we have the induction ring which uses a ring of negative energy to form a bubble of space around it which would enable it to move anywhere in the universe almost instantly

Then we have the diametric drive by creating a positive field behind the ship and a negative field behind it and rides the energy flow from one field to another

Lastly then bias drive which alters the properties of space itself, it would reduce the gravity in front of it and strengthen the gravity behind it so the ship would move to the lower gravity region
