---

I bought a new power supply for my desktop and when I try to boot my computer it freezes on the post screen, it also doesn't allow me to go into the bios. When I plug in my old power supply it works fine.

That said you could say "oh that's easy, it's the power supply" but I don't think so because I saw the power supply working fine in another computer.

It does this even if there is no hard drive hooked up.

I recently bought a video card for my computer, ATI 3650 to be exact (AGP). I thought my current power supply (250w) wasn't putting out enough power so I went looking for a new one and ended up with this one which is 400w.

Any ideas?

Specs for this computer can be found [here](#).
