[View Forum Message](#) <> [Reply to Message](#)

---

i am so P\*\*\*ed off with windows that i could lose all the work i currntly have just to get it off with my computer.

reason? i couldn't list there is so many things wrong with the windows generation.

first off windows is very unstable and crashes often, poeple can say this never happens but that is because they don't push like i do.

to stop it crashing at the moment i have overclocked the proccessor to the max and it over heats regulary. i have enough spyware to give tell the whole us when i go to the toilet.

i am going to install suse linux 9.1(i know it is a earlier version but i like it). i was wondering if there is a way to get rengaurd working with cedega. i was wondering if i run cedega twice once to run Game.exe and the second to run Game2.exe?

cedega runs renegade very well.

does anybody have problems with windows?

EG: you have renegade running in the background with rengaurd, renegade server is up and then level edit wont run or windows doesn't even seem to try and load it or it brings up a white window?

in suse linux if anything like that happens like the white screen it starts a crash handler that stops it \*IMMEDIETLY\* not it ten minits or an hour.

also the multitasking on suse linux is incredible, nothing windows could match. although i need windows for 3dsmax i can use Vmware which is good and windows seems to be more stable running in it.

ill post a screenshot of it later when i have everything installed.

I'm running Windows fine, currently my uptime is 5 weeks, 3 hours. I'm sure servers are up for longer, but as this is my home pc (And it isn't very good, still awaiting my new to arrive), I think its doing well.

nice.

would you be able to install it on my pc?(or at least lend me the disk )

i used to run linux(suse 9.1). the only reason i switched back to windows is cos i put a new motherboard in my pc, and had to reinstall an os. i didnt have a linux disk knocking around, but found a windows one.

as i said in my post i could bet you don't push it as much as i do, i normally have:renegadeserver, renegade+rengaurd, VC++, HLBot, 2 or 3 windows for browsing various files running. sometimes the window bar(blue bar at bottom) is so full i dont dont know what is running and what isn't i try to close programs but i need them lol.

i better make this short, the processor alarm is going off.

also thing i like about linux is i will let you try to force it to do something EG: you want to write a CD and there is no cd in the drive. it prompts you and there is a option to force and if you click it, it will send the data to the CD drive to burn.

i am still in the process of backing up so i wil have it installed in about 3 hours.

also the multitasking on suse linux is incredible, nothing windows could match. although i need windows for 3dsmax i can use Vmware which is good and windows seems to be more stable running in it.

ill post a screenshot of it later when i have everything installed.

I've been running Windows for years and have not had any "unknown problems". All the problems I have had with my computer were caused by me, and I know it. I have never had problems with Windows crashing, nor running slowly.

On the other hand, I don't see how you can possibly think overclocking your central processing unit is going to help.

And if you have spyware/viruses and other things, you really need to be more careful at what you browse on the internet, or stop looking at all that pr0n.

Heh, we all have our moments with it I'd guess. I haven't had many problems in a long time, apart from Nvidia drivers causing memory dumps every now and then...and I do push it quite a lot.

Anyway, in the end, it's not like the average gamer has much of a choice. That's what it always falls down to. I have about 30 games on my shelf (all legal retail versions by the way), and I might get maybe 30%-60% of them running on other operating systems with a lot of tweaking. Yes, there are emulators, and no, they're not stable. They also need a lot of tweaking to get the games working. In Windows, I install the game, and it just works. Expect this to be an even bigger "problem" when MS comes up with Direct X 10 (Vista only). I do have Ubuntu on my oldest PC, and I like it, but I don't like the idea of spending countless hours to figure out how to play a game.

like dan said, if you run windows through vmware, windows has major problems, all you have to do is delete the file it runs off and reinstall it. or, use cedega(it costs money - but i already have subscribed )

overclocking was need because windows couln't run all those programs well as it needs half for its core.

lol, i once installed windows. set it up so it was on the desktop, i went for my tea. 2 hours later(somthing come up) it would only boot into safe mode.

what do you think of that? also that stupid thing microsoft come up with caled activeX controls just calls for viruses and spyware.

it runs very fast on my computer as well, as it doen't have to waste CPU power loading grafix not to mention the ram it uses.

i hope vista doesn't sell as that will need a powerfull computer run, if you had a duel core processor it would just be as fast as if it was on windows xp with a 333MHz intel processor.

the only problem i can find with linux is it's lack of programs - which isnt too bad, and it's not exactly a bug, it's just people who create programs prefer to write ones for windows.

Windows has made a habit out of easy installs. It's nothing more than point, click, and maybe type in your name, organization, and how to identify your computer to a network.

I'm sure there's a more sensible fix than OCing, and as for spyware you need tools to protect your PC, it comes with the territory.

help-linux wrote on Sat, 09 September 2006 06:35

does anybody have problems with windows?

EG: you have renegade running in the background with rengaurd, renegade server is up and then level edit wont run or windows doesn't even seem to try and load it or it brings up a white window? Nope, never had anything like that.

Some people just don't like Windows, just like I'm not a big \*nix fan, but I use netBSD at Uni and this PC has been dual booted with Mandrake and SuSE and Ubuntu. I still go back to Windows because it's what im comfortable with.

when i have the processor clocking at what it was normally at it would crash very often making the computer un-useable so i couldn't even backup.

i had zone alarm security suit and that does work very well but some programs are not reconized as "viruses"

People who think Windows is a good operating system are nubcakes. You obviously have never used Linux before (especially with Xgl). I have both operating systems on a dual-boot. I used to use Linux full-time until a new compiz update messed up my key bindings. I was using the retarded quinnstorm version and I've just been too lazy to redo compiz... so I've been using Windows again for the past month or two. It's seriously a huge difference when you change your full-time operating system from Linux to Windows though. It's a big speed and stability difference.

And yes, I do know how to take care of Windows, but you can only help it so much.

"to stop it crashing at the moment i have overclocked the proccessor to the max and it over heats regulary. i have enough spyware to give tell the whole us when i go to the toilet."

Ever think that if you didn't make your computer run at a couple thousand degrees celcius that it wouldn't explode? Or about getting Spyware protection? If you screw hookers without protection, you get STDs, if you get the example.

I run Windows XP and always update it, and remove those babyish colors, and make it so all those extra features are disabled, so I basically have a "Windows 2000" type of look. It also increases performance. And it runs fine. I just hate calling support to authorize my serial, lol. It always asks me to re-auth my serial for "additional hardware installed to my pc" lol. Thats prob the only con i have

the windows system32 folder, which i would class as the kernel is bigger than the linux kernel.

the thing i like about the linux kernel is that it makes you wait when booting before you can do anything. this is good because you can't suddenly start throwing around commands while it is still loading and make it crash.

Mac's are only built and designed with their counterpart machines. They make their own computers as well as make the software but Mac's are mainly used for media like video editing and music editing and stuff.

Our school just got a PowerMac G5 for the studio and it's absolutly great.

On MacOS: It's great, I run a quad-boot on my PC with XP, Vista, Ubuntu and MacOSX 10.4.6 That's right, you can run MacOS on pretty much ANY computer now! Just take a look at [www.osx86project.org](http://www.osx86project.org), it has guides and links to all you need to run MacOS on your normal computer (provided you have MacOS on a DVD, of course )

On Linux: It's great..etc.

However, all the crapola about dependancies really does annoy me, if I want to install a program on Linux there's a good chance I'll either have to "apt-get install" the dependancies, or, because that's often not worked, find them manually on the internet and compile/install them. Another thing that annoys me is Xgl/Compiz. I have to admit, the effects are pretty cool, but only if you have a decent graphics card that someone can be bothered to make Linux drivers for, and besides, I hate anything that doesn't have Antialiasing nowadays. Oh, and it's far from finished, and plays Videos and other graphicky things rubbishly.

On Windows: I don't see why everyone hates it so much! I have a Sempron64 3400+ with 512Mb RAM and I've probably had more crashes on Ubuntu/MacOS than on Windows. I've never had a single virus/spyware (Of course, that depends on the websites one visits!) and it hardly ever seems slow or sluggish without me accidentally putting an infinite loop in a script or something.

All in all, I think Ubuntu and MacOS both have great potential, as does Vista, but, at the moment, there simply isn't enough worldwide support or programs to make them a completely viable solution for me.

Therefore, I'll stick with what I got now.

Although...

Has anyone actually got Renegade/RenGuard/WOL working under Cedega? I don't like Cedega (Crap license, Open Source all the way!) but I do use it.

I'm sure servers are up for longer, but as this is my home pc (And it isn't very good, still awaiting my new to arrive), I think its doing well.

as i said in my post i could bet you don't push it as much as i do, i normally have:renegadeserver, renegade+rengaurd, VC++, HlBot, 2 or 3 windows for browsing various files running. sometimes the window bar(blue bar at bottom) is so full i dont dont know what is running and what isn't i try to close programs but i need them lol.

Lets see what programs...

- IDA x2 (One for RenegadeFDS on windows, one for Linux)
- mIRC x2( I should use just one but I don't)
- RenegadeServer
- RenGuard + Renegade
- Visual Studio

And my processor is only 2.40GHz

i got renegade working on cedega with WOL. unfortunately, i couldnt install RG, as the way cedega installs programs is it creates a new virtual c: drive for all the games instead of just installing them to the same virtual drive.

If ubuntu messes up on you, it's because you set it up wrong.

I have Xgl and I can run MULTIPLE H.264 videos at decent resolutions and overlap them, make them transparent, and do all kinds of other stuff with them and they don't lag. In Windows, ONE H.264 video that is a pretty decent resolution will lag a whole lot for me. There's nothing more to say here.

I don't see what's wrong with apt-get install. It works perfectly fine for me. I think it's nice because I can easily find a free program with a package manager, instead of having to search Google (and most likely find a trial).

Question is, do I want to run multiple overlapped transparent H.234 videos?

EDIT: Nevertheless, I'm interested. Do you have an nVidia card? I have a GeForce 6200, I can run a HD video \*fairly\* fine in XP, but in Xgl I can't seem to find a working video output thingy. Then again, I haven't tried for a few months now, there's probably been a few thousand updates.

You mean H.264. H.264 is probably the best video compressing codec out there right now and it is very powerful. It uses a crapload of CPU to decode.

I have a Geforce 6800. I used to have problems getting video to work in Xgl/compiz, but after a new version of Ubuntu it randomly seemed to work fine. Remember though, Xgl is totally new and it's not even in beta.

Anyways, I'm installing Xgl and compiz now. Hopefully, the videos will work better on Dapper than they did on Breezy...

On Cedega: Every time I try to install Renegade, I set everything up but when the installer's actually supposed to start nothing seems to happen. Do I have to try and use that non-graphical installer someone made, or is my computer b0rked?

Also, is everyone here using KDE, or are there some GNOME users other than me?

EDIT: OK, I changed some things, and now I can get as far as installing the game. However, when it actually starts copying the files, it says that "TDBERR" is copying and locks up before the little rotating soldier appears, so I still can't finish the install.

I use Gnome.

just so you know, you can't count on getting Renegade to work in Cedega if you have Xgl/compiz. Because right now direct rendering is not supported in Xgl. But if the nVIDIA drivers for Xorg 7.1 EVER COME OUT, then that will change. I can't even believe ATi released Linux drivers for Xorg 7.1 before nVIDIA.

There are pros and cons to every operating system. Being a network security analyst I know many of the geek details to many operating systems and I can honestly say that Windows is one hell of a resource waster.

HOWEVER, \*nix hasn't seemed to have developed yet. At least in the last few years you have WINE and other emulations and a greater drive for people to develop compatibility with games and such. Unix is a nice system if you're doing anything that doesn't require a great deal of compatibility or requires a great deal of security. Windows is pretty much the opposite.

I hear people bash Windows all the time, but they don't consider things like the brilliance of developing a user friendly GUI for an operating system; or how far Microsoft has gone to develop cross-platform technologies. Though I'm not a huge M\$ fan in general, I am not sold on \*nix quite yet either. It still needs more development. You may not like M\$ in general - or perhaps it is just a hate for their Windows OS product line, but before you go bashing Windows consider that many people use it for the simple fact that there isn't much that can challenge it right now.

I wasn't saying it was, but I was suggesting that it is similar to products like VMware which is. WINE is similar in the sense that it allows you to "emulate" an operating system on top of an operating system -- you know what I mean

I don't bash Windows mindlessly, nor do I bash the living hell out of it. It may seem like I'm one of those band riders that love Linux and hate Microsoft, but I'm not trying to be like everyone else.

---

It's not because someone told me so, it's because I use both and I've figured out myself.

Yes, Linux is still in development, but it's impressive where it's at right now and how it is still getting better. The distro I use noticeably gets better monthly. Plus, it's free.

I can't even believe ATi released Linux drivers for Xorg 7.1 before nVIDIA.

Aha, I got around that problem by creating an Xgl server at tty7 with compiz etc. and a normal Xorg server at tty8, both at the same time. That way, I can use tty8 for stuff that needs Direct Rendering, and tty7 for everything else. It doesn't create a noticeable performance decrease, either.

My problem still remains, though. (the one where the installer crashes as it starts to copy the files) How did you people go about installing it? If I can get Renegade to work here, who knows, I might be able to get rid of Windows altogether!

Well, neither am I () but if you have Ubuntu (well, I guess this will work on other distros) then I used this guide.

Still got to make it install, though.

I got a chance to participate in the London Imperial College annual software developer showcase. They had several mainstream developers there show, some of which were discussing how the new upcoming Linux updates were shaping up. You'll be surprised how many problems and issues they ran in to. Linux is very powerful and bus friendly when controlling data but it lacks the robustness that Windows has.

Windows 2003 is a very stable operating system, that and the fact it is actually a better environment to design and develop software in than Linux. I use both platforms extensively, both have their uses and in my opinion there is no better operating system; they are both tools, and all tools are useful in given situation.

Also regarding the overclocking the processor to ensure stability. You'd gain 5% real-world difference in performance in Windows, Windows uses very little processing cycle time as it is, instead Windows consumes your memory. I was even talking to someone from the animation team this morning and they laughed when I mentioned your claim at overclocking to remain stable.

At work, I have 4 Windows platforms for developing different software, one is dual core and overclocked. At home I have a phase-cooled AMD Athlon 64 X2 FX62 running 24/7 at 3.4 GHz. I notice no difference in multi-tasking or running any real-world applications; even then I only notice a difference in FPS.

I'm sorry, but according to my experiences with using Windows XP and Linux, I've had better results in Linux with just about everything.

The only thing that's really lame in my opinion is that video editing on Linux just doesn't really exist.

you (or anyone) can laugh all you want because it made it fast enough to backup all my stuff. i tried before overclocking and it wouldn't do it. it just kept locking up.

with linux, if a program locks up i can go into runlevel 3 and stop its process. if it crashes in windows there is not much you can do except wait for task manager to come up.

I might have a solution for the cant install renegade thingy in linux, but I don't know wheter or not you can emulate/import registry files as that will be neacetary

1. Make sure you already have a renegade install.
2. Edit the registry files to contain the serial and the right game path.
3. Import the registry settings.

Then I guess it should work, atleast thats how I installed renegade here on windows

### File Attachments

1) [renegade.cleaned.reg](#), downloaded 86 times

Those definitely helped, and I can actually get into Renegade now (), but I still can't log on to XWIS, I get the "invalid serial" error.

I've tried putting the right registry keys pretty much everywhere, running the Serial Changer under Wine, and probably a lot more, but I can't seem to get it to work...

Depending on how you use Windows, and the version you use will ultimately effect it's security. I've been using windows for 7 years now and not once has it spontaneously crashed with no cause. You must be calling for more resources than windows can handle.

Download and install Vista RC1 on a small test machine and use that for whatever, Maybe the Fraps and Vegas video editing software you called for?

your right...in all my life windows has never crashed without a unown cause. but i have had it with the amount of crap i get from it.

take this for example:

i was installing VMWare while i was playing world of warcraft, WoW doesn't take much to run...it uses the same principle as renegade in rendering terrain etc... (although i don't know much about it, the character and the terrain look surprisingly similar)

as soon as the installer took too much of the CPU it completely locked up, i couldn't even turn it off (using acpi). i had to cut the power.

it gets very slow when trying to do 2 tasks like open IE while starting endorphin for example, IE will be up straight away normally.

now, here is where linux completely overrules windows:

1) if there is a lockup like then WoW crashed KDE will come in and save you. if KDE crashes, press F2 or ctrl+F2 (i can't remember exactly) and you're in the completely in the kernel. you can do "ps aux | grep "programname" then do "kill process id" to kill it. then restart "x".

2) the windows task manager is too primitive, if the computer locks up you can't kill anything because there is a chance task manager will crash (that has happened many times).

3) linux doesn't have a "Windows error" that tells nothing about what has happened, and if you "Send" you get no support anyway. linux will tell you about what has actually happened with a program and will kill it FOR you.

4) most newer distros are VERY user-friendly and come ready for a simple user to use.

5) linux is very powerful, stable, reliable and best of all FREE!

6) linux is very customizable, you see something in a program you don't like or you want the kernel to load something that you have written, no problem! the sources are available for download and it is EASY to compile and replace the old kernel.

7) more secure, the distro that i use comes with an excellent firewall, i never have problems with "hackers".

viruses, because most viruses these days are active-x on website people just install them not knowing what they are doing, although viruses are a threat because of the way the linux kernel works it would take a hacker or an incredible stupid user to install one.

linux disadvantages:

1) not many programs (like games and newer, cpu intensive stuff) are not made for linux.

2) programs need dependencies and some can be very hard to find.

3) some programs are hard to install, most need to be done from the command line but commands just need to be learned.

windows advantages:

1) a lot of programs are made for it.

2) programs are easy to install

windows disadvantages:

1) VIRUSES, HACKERS...very easy to get into a windows machine.

2) not as user friendly as you think, how do i stop people from going into a folder IE they need a

password?

3) windows costs 80 bucks.

4) windows is all about presentaion using valuable RAM for "fancy" pictures and animations (this also uses CPU to load them)

5) windows assumes the user is extremely stupid and pops up with messages saying "you need to restart your computer" why? why do i need to restart my computer...then it does it anyway and you lose an hours worth of work. (this has happend many times for me)

6) windows multitaking is diabolical.

7) you cant change how the "innards" of it work

everything you do on windows is ilegal

9) nothing (with the exeption of 1 in 10000 programs are open source)

10) the list goes on and on and on and on.

oh, and people are intitled to opionins and experience with windows. some people are lucky it like the hardware they have and may run quite well.

BUT...windows vista is out of the question, mabe when it comes out and i can pirate it and put it on VMware but otherwise NTLDR isnt going near my HDD's MBR. im not going to torcher it.

im not trying to persuade people to go over to linux, because im not botherd about peoples closed mindeness. but if they wanted to try it, download VMware player and i can setup a machine for it ready for a install.

I can't say that Windows has ever randomly crashed for no reason, because there's always some process running that can hang.

Also, I get the feeling a lot of the trouble Windows gets is from people writing crappy programs for it, along with the fact it can't really handle them as well as Linux. If I pay £40 for ZoneAlarm Pro (Not that I have) I expect it to work, but the copy my mother bought randomly uses 100% of the CPU when another program crashes, and because of the security measures I can't end it from Task Manager.

(In conclusion, I'm blaming some of the crappyness on Windows, and some on software devs.)

It can, you just have to enable it. I don't remember where you can enable it, but System Mechanic has an option that can enable this for you, and there is a API call you can use if you write a small program. You will have to dig deep into MSDN to find it, though.

There is another setting for it, that is always enabled, and cannot be disabled. Sometimes, when I have allot of spyware, and run Ad-Aware, this little window pops up says the computer will be shutdown in 60 seconds. Maybe cause a certain file has been opened up.

And when my PSU failed on my old computer, it gave me a warning that in 5 minutes your computer will shutdown and crash.

A faulty PSU can caus alot of problems. Also making your Windows unstable. But I'd say 90% of the users having problems with Windows are just handling it wrong. (using p2p and browsing the wrong sites, illigal software/cracked hey no wonder it gets unstable then.)

How is the chance 0, do you realize how many people use some cheap case with a cheap powersupply in it that says 500watt but it actually delivers the half or less? One of the most important PC parts is actually a powersupply (When it comes to stability) because that it what gives the voltage to all hardware in it if not delivering sufficient making it unstable and giving BSOD and what not.

gamemodding wrote on Sun, 17 December 2006 11:04 ofc it can, but really...the chance of it hapening are just about 0. if it does, your motherbaord should report it, unless that is faulty as well.

Your motherboard does not report it as in an error code the only reason you'll see it reported is that when it won't boot up anymore or when it inflicted major damage due to insufficient power.

You can however take a look at the hardware monitor in your bios and look up to the voltages that your PSU give. And if it's not within range then you can take a look at it with a fluke meter since the BIOS is not always accurate.

Quote:first off windows is very unstable and crashes often, poeple can say this never happens but that is because they don't push like i do.

If you have powerful enough hardware, correct drivers, good configuration and stable software there will be no problems. Your "pushing" implies that somehow you are hitting a software bottleneck. Id love to know what that is.

Quote:i have overclocked the proccessor to the max and it over heats regulary. i have enough spyware to give tell the whole us when i go to the toilet.

First off, overclocking your CPU will cause all sorts of problems if you do not do it properly. How can you expect any OS to run on dodgy hardware? It cannot. If you have spyware then that's your fault. I hav eWindows installed here and it is not riddled with spyware.

Quote:I was wondering if there is a way to get rengaurd working with cedega. i was wondering if i run cedega twice once to run Game.exe and the second to run Game2.exe?

Havent heard of a way but if you find a way please let us know. I too run openSUSE. Of course I have Windows too because of Rengaurd.

Quote:cedega runs renegade very well.

Indeed

Quote:does anybody have problems with windows?

It all depends what people are after in an OS. Sure I have problems and they are generally around lack of built in programs that I require. For example, \*nix has the ability to chain commands together. For example if I want to see how many Apache (httpd) processes I am running, I can tell \*nix to find all of the running processes, find all of the httpd ones, then do a line count. Output is simply the number. How do I do that in Windows? I have no idea. I would probably have to script it.

Quote:in suse linux if anything like that happens like the white screen it starts a crash handler that stops it \*IMMEDIETLY\* not it ten minits or an hour.

The kernel is different... and events are different. You can tune this in Windows but its not great by any means.

Quote:also the multitasking on suse linux is incredible, nothing windows could match. although i need windows for 3dsmax i can use Vmware which is good and windows seems to be more stable running in it.

Really? Both are multitasking and both do it diffently. Mute point really. If your Windows is running better in a VM it does rather point to dodgy windows drivers when you run it natively.

Give it time and I am sure you will have equal frustrations with Suse. The point I am making is that each OS is different however they both require management on the user's part. It is impossible to say which is "better" or more "secure". Obviously this arguement is nothing new. However, if suse meets your requirements more than Windows does then great.

Quote:hehe, not only that people want STABILITY which windows lacks. you need STABILITY in a server.

I run Windows and Solaris servers. To be honest Solaris has more uptime. Why? Well to be perfectly honest its always (to date) a hardware problem. The HP servers that run Windows are nearly always failing with NIC problems. They have dual nics, but they are built in to the motherboard. This means we have to take down the server and replace the mobo. So far, Sun hardware hasnt been a problem. As far as the OS goes, no problems so far.

I just checked the services bounce stats and they are fairly even. Windows is slightly higher but thats because they are running IBM WebSphere which seems to have a habit of getting java.exe to do crazy memory things. So all in all, OS-wise they are pretty even.

the last thing i forgot to add.

windows lacks hardware support. i know this is an issue because of hardware, thats why my comp works so well with Suse. what i ment by multitasking is suse handles it better, for one: it can detect a crash and end it. 2 if there is a crash and everything is locked up you can switch to the kernel and end the offender. 3 everything just seems to work better, what i found was. i could burn 2 disks at once while running loads of "Konquers" loads of Terminals installing stuff. i could switch between each one without a problem. windows however, if a program get stuck in a loop (in the

code) the program locks up. i found with suse however it doesn't, and after about 30 secs KDE ends it anyway. can you do that with windows? the answer is yes, but instead of ending it instantly it tries to end it by "virtually" clicking the "X" symble, how stupid is that? you have to end its process manually before it will close. as soon as i sort this computer out again im going to move over to suse. and not run rengard, i don't use it atm anyway because "i have a currupt always.dat". i have bought the game so i should be able to play soon.

im sure the reason rengaurd wont run with cedega is because it is missing dependancys. you need that service, whatever it is called. it should work with the new rengaurd update.

one last thing, because linux doesn't support .NET or active X it is not possible to get viruses of just browsing the net. i have also found you cant get them in music files, documents or pictures. you would have to download one and INSTALL it before it would do anything. and then, most of the things you download for linux have a checksum so you know it doesn't have virusus embedded. unless of course the developer has put some in the program.

linux has 2 flaws though:

- 1) its not very user freindly as in you would have to learn SH to use the terminal.
- 2) at the moment, not many programs are being developed for it. although there are emulators, if someone decided to bring out a game for linux i would buy it
- 3) installing some programs is hard, some dependancys are a really tuffy to find, and some of them need dependancys.

but thats all i don't like about it.
