Most text editors (Notepad, Wordpad, etc.) can open and edit PHP files.

If you're trying to steal someone's script from their website then you're out of luck. When you request the script from the server it is parsed and the results are sent back.

Unless you can download the script in a zip, or have access to the server files and can download it through FTP or SSH or something, you cant get the actual PHP file. You will just get HTML and the results of what the script was supposed to do.
